## CMOS Low-Power Monostable/Astable Multivibrator

### High Voltage Types (20-Volt Rating)

■ CD4047B consists of a gatable astable multivibrator with logic techniques incorporated to permit positive or negative edge-triggered monostable multivibrator action with retriggering and external counting options.

Inputs include +TRIGGER, -TRIGGER, ASTABLE, ASTABLE, RETRIGGER, and EXTERNAL RESET. Buffered outputs are Q, Q-bar, and OSCILLATOR. In all modes of operation, and external capacitor must be connected between C-Timing and RC-Common terminals, and an external resistor must be connected between the R-Timing and RC-Common terminals.

Astable operation is enabled by a high level on the ASTABLE input or a low level on the ASTABLE input, or both. The period of the square wave at the Q and Q-bar Outputs in this mode of operation is a function of the external components employed. "True" input pulses on the ASTABLE input or "Complement" pulses on the ASTABLE input allow the circuit to be used as a gatable multivibrator. The OSCILLATOR output period will be half of the Q terminal output in the astable mode. However, a 50% duty cycle is not guaranteed at this output.

The CD4047B triggers in the monostable mode when a positive-going edge occurs on the +TRIGGER-input while the -TRIGGER is held low. Input pulses may be of any duration relative to the output pulse.

If retrigger capability is desired, the RETRIGGER input is pulsed. The retriggerable mode of operation is limited to positive-going edge. The CD4047B will retrigger as long as the RETRIGGER-input is high, with or without transitions (See Fig. 34).

An external countdown option can be implemented by coupling "Q" to an external "N" counter and resetting the counter with the trigger pulse. The counter output pulse is fed back to the ASTABLE input and has a duration equal to N times the period of the multivibrator.

A high level on the EXTERNAL RESET input assures no output pulse during an "ON" power condition. This input can also be activated to terminate the output pulse at any time. For monostable operation, whenever V<sub>DD</sub> is applied, an internal power-on reset circuit will clock the Q output low within one output period (t<sub>M</sub>).

The CD4047B-Series types are supplied in 14-lead hermetic dual-in-line ceramic packages (D and F suffixes), 14-lead dual-in-line plastic packages (E suffix), 14-lead small-outline package (NSR suffix), and in chip form (H suffix).

### Features:

- Low power consumption: special CMOS oscillator configuration
- Monostable (one-shot) or astable (free-running) operation
- True and complemented buffered outputs
- Only one external R and C required
- Buffered inputs
- 100% tested for quiescent current at 20 V
- Standardized, symmetrical output characteristics
- 5-V, 10-V, and 15-V parametric ratings
- Meets all requirements of JEDEC Tentative Standard No. 13B, "Standard Specifications for Description of 'B' Series CMOS Devices"

### Monostable Multivibrator Features:

- Positive- or negative-edge trigger
- Output pulse width independent of trigger pulse duration
- Retriggerable option for pulse width expansion
- Internal power-on reset circuit
- Long pulse widths possible using small RC components by means of external counter provision
- Fast recovery time essentially independent of pulse width
- Pulse-width accuracy maintained at duty cycles approaching 100%

### Astable Multivibrator Features:

- Free-running or gatable operating modes
- 50% duty cycle

- Oscillator output available
- Good astable frequency stability:  
Frequency deviation:  
= ±2% + 0.03%/°C @ 100 kHz  
= ±0.5% + 0.015%/°C @ 10 kHz  
(circuits "trimmed" to frequency  
V<sub>DD</sub> = 10 V ± 10%)

### Applications:

- Digital equipment where low-power dissipation and/or high noise immunity are primary design requirements:
- Envelope detection
  - Frequency multiplication
  - Frequency division
  - Frequency discriminators
  - Timing circuits
  - Time-delay applications

### RECOMMENDED OPERATING CONDITIONS

For maximum reliability, nominal operating conditions should be selected so that operation is always within the following ranges:

CHARACTERISTIC	LIMITS		UNITS
	MIN.	MAX.	
Supply-Voltage Range (For T <sub>A</sub> = Full Package-Temperature Range)	3	18	V

NOTE: IF AT 15 V OPERATION A 10 MΩ RESISTOR IS USED THE OPERATING TEMPERATURE SHOULD BE BETWEEN -25°C and 100°C

### MAXIMUM RATINGS, Absolute-Maximum Values:

DC SUPPLY-VOLTAGE RANGE, (V <sub>DD</sub> ) Voltages referenced to V <sub>SS</sub> Terminal)	-0.5V to +20V
INPUT VOLTAGE RANGE, ALL INPUTS	-0.5V to V <sub>DD</sub> +0.5V
DC INPUT CURRENT, ANY ONE INPUT	±10mA
POWER DISSIPATION PER PACKAGE (P <sub>D</sub> ): For T <sub>A</sub> = -55°C to +100°C	500mW
For T <sub>A</sub> = +100°C to +125°C	Derate Linearly at 12mW/°C to 200mW
DEVICE DISSIPATION PER OUTPUT TRANSISTOR FOR T <sub>A</sub> = FULL PACKAGE-TEMPERATURE RANGE (All Package Types)	100mW
OPERATING-TEMPERATURE RANGE (T <sub>A</sub> )	-55°C to +125°C
STORAGE TEMPERATURE RANGE (T <sub>stg</sub> )	-65°C to +150°C
LEAD TEMPERATURE (DURING SOLDERING): At distance 1/16 ± 1/32 inch (1.59 ± 0.79mm) from case for 10s max	+265°C

## 1. Astable Mode Design Information

### A. Unit-to-Unit Transfer-Voltage

**Variations** — The following analysis presents variations from unit to unit as a function of transfer-voltage ( $V_{TR}$ ) shift (33%—67%  $V_{DD}$ ) for free-running (astable) operation.

Fig. 32—Astable mode waveforms.

$$t_1 = -RC \ln \frac{V_{TR}}{V_{DD} + V_{TR}};$$

typically,  $t_1 = 1.1 RC$

$$t_2 = -RC \ln \frac{V_{DD} - V_{TR}}{2V_{DD} - V_{TR}};$$

typically,  $t_2 = 1.1 RC$

$$t_A = 2(t_1 + t_2)$$

$$= -2 RC \ln \frac{(V_{TR}V_{DD} - V_{TR})}{(V_{DD} + V_{TR})(2V_{DD} - V_{TR})}$$

Typ: $V_{TR} = 0.5 V_{DD}$	$t_A = 4.40 RC$
Min: $V_{TR} = 0.33 V_{DD}$	$t_A = 4.62 RC$
Max: $V_{TR} = 0.67 V_{DD}$	$t_A = 4.62 RC$

thus if  $t_A = 4.40 RC$  is used, the variation will be +5%, -0% due to variations in transfer voltage.

**B. Variations Due to  $V_{DD}$  and Temperature Changes** — In addition to variations from unit to unit, the astable period varies with  $V_{DD}$  and temperature. Typical variations are presented in graphical form in Figs. 11 to 18 with 10% as reference for voltage variations curves and 25°C as reference for temperature variations curves.

### ii. Monostable Mode Design Information

The following analysis presents variations from unit to unit as a function of transfer-voltage ( $V_{TR}$ ) shift (33% — 67%  $V_{DD}$ ) for one-shot (monostable) operation.

Fig. 33—Monostable waveforms.

$$t_1' = -RC \ln \frac{V_{TR}}{2V_{DD}}$$

typically,  $t_1' = 1.38 RC$

$$t_M = (t_1' + t_2)$$

$$t_M = -RC \ln \frac{(V_{TR})(V_{DD} - V_{TR})}{(2V_{DD} - V_{TR})(2V_{DD})}$$

where  $t_M$  = Monostable mode pulse width. Values for  $t_M$  are as follows:

Typ: $V_{TR} = 0.5 V_{DD}$	$t_M = 2.48 RC$
Min: $V_{TR} = 0.33 V_{DD}$	$t_M = 2.71 RC$
Max: $V_{TR} = 0.67 V_{DD}$	$t_M = 2.48 RC$

thus if  $t_M = 2.48 RC$  is used, the variation will be +9.3%, -0% due to variations in transfer voltage.

#### Note:

In the astable mode, the first positive half cycle has a duration of  $t_M$ ; succeeding durations are  $t_A/2$ .

In addition to variations from unit to unit, the monostable pulse width varies with  $V_{DD}$  and temperature. These variations are presented in graphical form in Fig. 19 to 26 with 10 V as reference for voltage-variation curves and 25°C as reference for temperature-variation curves.

COMMERCIAL CMOS  
HIGH VOLTAGE ICs

## CD4047B Types

### III. Retrigger Mode Operation

The CD4047B can be used in the retrigger mode to extend the output-pulse duration, or to compare the frequency of an input signal with that of the internal oscillator. In the retrigger mode the input pulse is applied to terminal 12, and the output is taken from terminal 10 or 11. As shown in Fig. 34 normal monostable action is obtained when one retrigger pulse is applied. Extended pulse duration is obtained when more than one pulse is applied.

Fig. 34—Retrigger-mode waveforms.

For two input pulses,  $t_{RE} = t_1' + t_1 + 2t_2$ . For more than two pulses, the output pulse width is an integral number of time periods, with the first time period being  $t_1' + t_2$ , typically,  $2.48RC$ , and all subsequent time periods being  $t_1 + t_2$ , typically,  $2.2RC$ .

### IV. External Counter Option

Time  $t_M$  can be extended by any amount with the use of external counting circuitry.

Advantages include digitally controlled pulse duration, small timing capacitors for long time periods, and extremely fast recovery time. A typical implementation is shown in Fig. 35. The pulse duration at the output is

$$t_{ext} = (N - 1)(t_A) + (t_M + t_A/2)$$

where  $t_{ext}$  = pulse duration of the circuitry, and  $N$  is the number of counts used.

92CS-29041

Fig. 35—Implementation of external counter option.

### V. Timing-Component Limitations

The capacitor used in the circuit should be non-polarized and have low leakage (i.e. the parallel resistance of the capacitor should be at least an order of magnitude greater than the external resistor used). There is no upper or lower limit for either  $R$  or  $C$  value to maintain oscillation.

However, in consideration of accuracy,  $C$  must be much larger than the inherent stray capacitance in the system (unless this capacitance can be measured and taken into account).  $R$  must be much

larger than the CMOS "ON" resistance in series with it, which typically is hundreds of ohms. In addition, with very large values of  $R$ , some short-term instability with respect to time may be noted.

The recommended values for these components to maintain agreement with

tion of leakage current in the circuit, as shown in the static electrical characteristics. For dynamic operation, the power needed to charge the external timing capacitor  $C$  is given by the following formulae:

Astable Mode:

$$P = 2CV^2f \text{ (Output at terminal No. 13)}$$

$$P = 4CV^2f \text{ (Output at terminal Nos. 10 and 11)}$$

Monostable Mode:

$$P = \frac{(2.9CV^2)(\text{Duty Cycle})}{T}$$

(Output at terminal Nos. 10 and 11)

The circuit is designed so that most of the total power is consumed in the external components. In practice, the lower the values of frequency and voltage used, the closer the actual power dissipation will be to the calculated value.

Because the power dissipation does not depend on  $R$ , a design for minimum power dissipation would be a small value of  $C$ . The value of  $R$  would depend on the desired period (within the limitations discussed above). See Figs. 27, 28, and 29 for typical power consumption in astable mode.

previously calculated formulas without trimming should be:

$C \geq 100 \text{ pF}$ , up to any practical value, for astable modes;

$C \geq 1000 \text{ pF}$ , up to any practical value for monostable modes.

$$10 \text{ k}\Omega \leq R \leq 1 \text{ M}\Omega$$

### VI. Power Consumption

In the standby mode (Monostable or Astable), power dissipation will be a func-

Chip dimensions and pad layout for CD4047B
